**Introduction:** Automated analysis of Ki67 expression is more and more commonly used in the daily routine diagnostics and prognostics of canine mast cell tumors. The purpose of this study was to compare different methods within the same tumour cohort and to find a practicable approach for the daily diagnostic routine

**Materials and Methods:** FFPE tissue from 78 archived canine mast cell tumors served as material. Slides were reviewed and separated in two groups (cutaneous and subcutaneous), cutaneous were graded according to Patnaik and Kiupel <sup>1,2</sup>. Routinely Giemsa and Ki67 stained slides were scanned and aligned using Visiopharm® for selection of tumour tissue. Ki67 positive nuclei were counted on the whole slide (output: % of total nuclei) using different methods followed by construction of a heat map. Positive cells were then counted in the hot spots according to published literature for manual and automated counting.

**Table 1:** Workflow of Ki67 counting

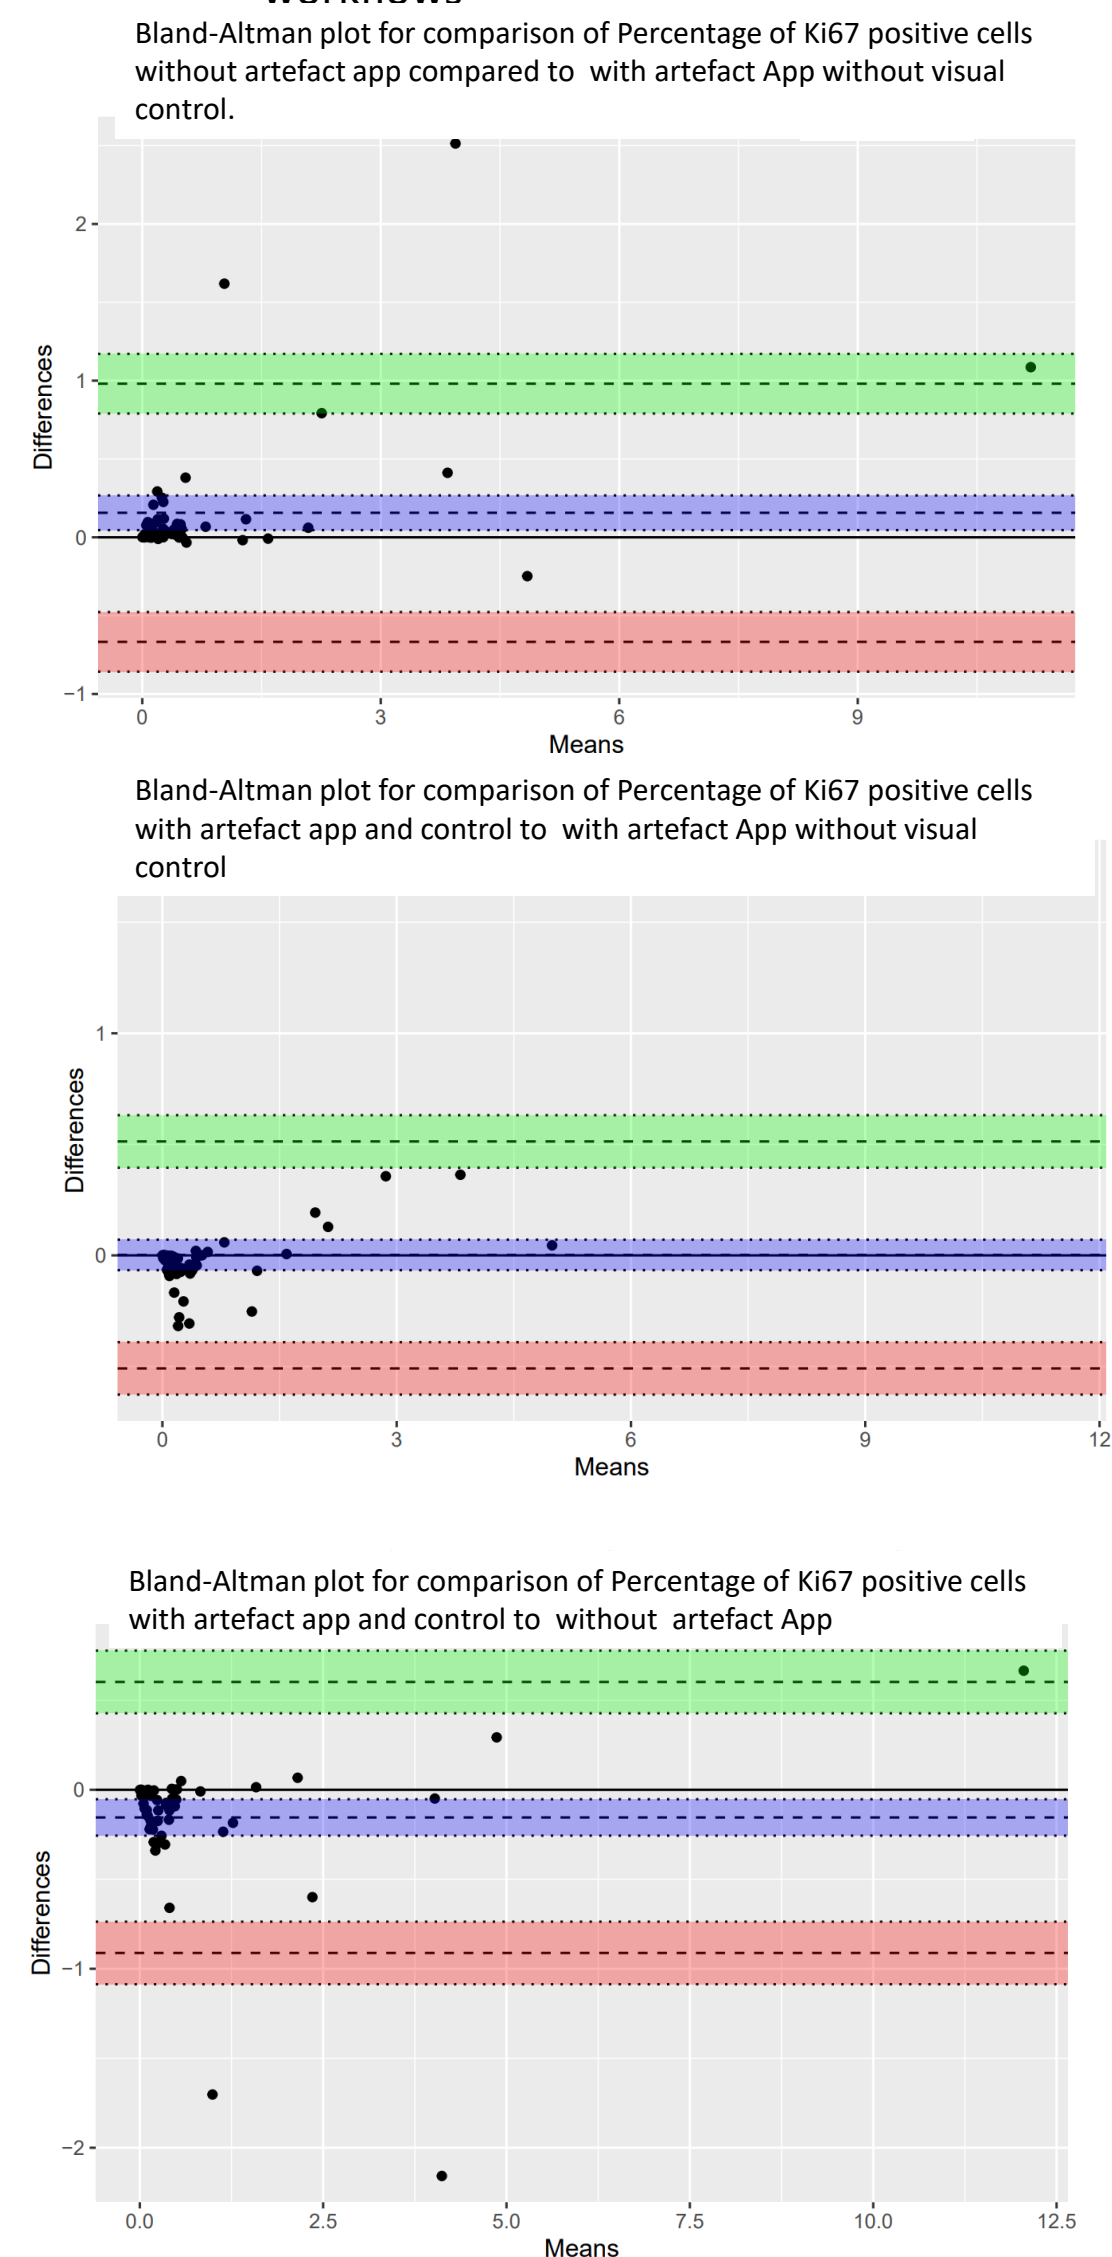

## Results:

**Table 2** Comparison of percentage of Ki67 positive cells over the whole tumor with/ without artefact exclusion (image a-f table 1)

Case Number	Percentage positive cases without artifact	Percentage positive cases with artifact	Percentage positive cases with artifact and visual control

## Conclusions:

This study underlines the need of a standardized approach for the automated Ki67 counting in mast cell tumours among pathologists, which allows comparison of different methods<sup>3,4</sup> with fewer resources. Examination of a larger cohort with clinical data is now needed to compare the different methods. Techniques published for the microscopic evaluation pose some difficulties when transferred to the automatic counting. In addition, transparent communication and close collaboration with the laboratory is needed to minimize preanalytical issues and thereby saves pathologists time and costs.
